

The Riemann-Stieltjes Integral

The Riemann-Stieltjes Integral is a generalization of the Riemann Integral.

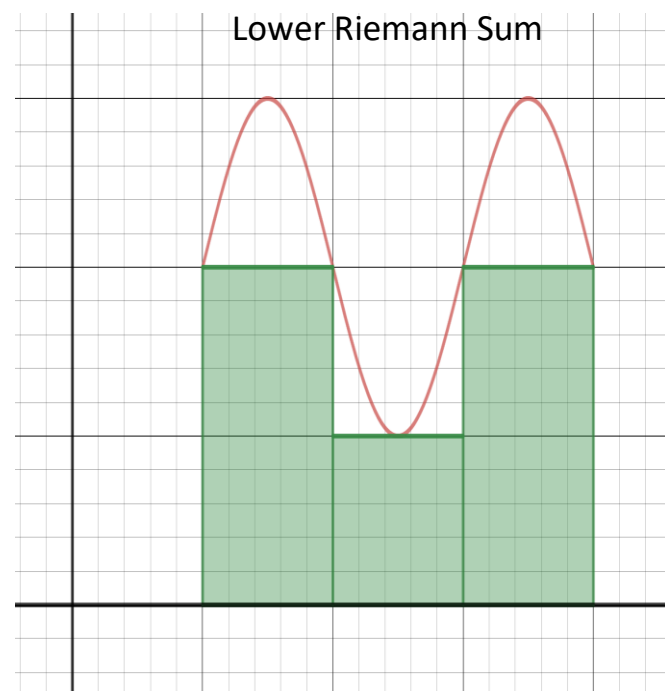

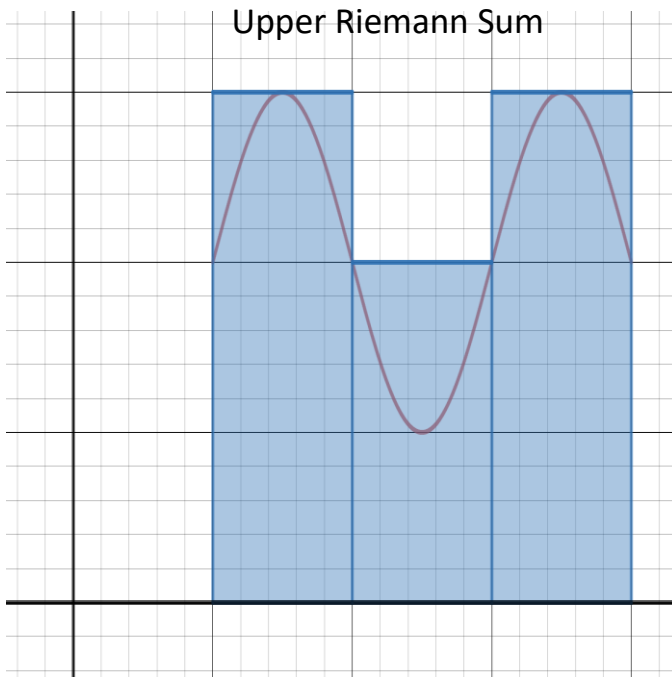

In the Riemann integral of a bounded function f we partition an interval $[a, b]$ into $a = x_0 < x_1 < x_2 < \dots < x_n = b$. We then consider the upper and lower sums:

$$U(f, [a, b]) = \sum_{i=1}^n M_i (x_i - x_{i-1})$$

$$L(f, [a, b]) = \sum_{i=1}^n m_i (x_i - x_{i-1})$$

Where $M_i = \sup\{f(x) \mid x_{i-1} \leq x \leq x_i\}$

$m_i = \inf\{f(x) \mid x_{i-1} \leq x \leq x_i\}$.

We define the lower and upper Riemann integrals by:

$$\int_{-a}^b f dx = \sup_P \{L(f, P) \mid P \text{ a partition of } [a, b]\}$$

$$\int_a^{\bar{b}} f dx = \inf_P \{U(f, P) \mid P \text{ a partition of } [a, b]\}.$$

Since f is bounded and $[a, b]$ has finite length, $-\infty < L(f, P) \leq U(f, P) < \infty$ and $-\infty < \int_{-a}^b f dx \leq \int_a^{\bar{b}} f dx < \infty$.

If $\int_{-a}^b f dx = \int_a^{\bar{b}} f dx$ we say that f is Riemann integrable over $[a, b]$ and $\int_a^b f dx = \int_{-a}^b f dx = \int_a^{\bar{b}} f dx$.

For a Riemann-Stieltjes integral of a bounded function f on $[a, b]$, we will start with an increasing function α on $[a, b]$. We then consider the upper and lower sums:

$$U_\alpha(f, [a, b]) = \sum_{i=1}^n M_i(\alpha(x_i) - \alpha(x_{i-1}))$$

$$L_\alpha(f, [a, b]) = \sum_{i=1}^n m_i(\alpha(x_i) - \alpha(x_{i-1}))$$

where $M_i = \sup\{f(x) \mid x_{i-1} \leq x \leq x_i\}$

$$m_i = \inf\{f(x) \mid x_{i-1} \leq x \leq x_i\}.$$

Notice that $U_\alpha(f, [a, b]) \geq L_\alpha(f, [a, b])$.

We define the lower and upper Riemann-Stieltjes integrals by:

$$\int_{-a}^b f d\alpha = \sup_P \{L_\alpha(f, P) \mid P \text{ a partition of } [a, b]\}$$

$$\int_a^{\bar{b}} f d\alpha = \inf_P \{U_\alpha(f, P) \mid P \text{ a partition of } [a, b]\}.$$

Since f and α are bounded and $[a, b]$ has finite length,

$$-\infty < L_\alpha(f, P) \leq U_\alpha(f, P) < \infty \text{ and } -\infty < \int_{-a}^b f d\alpha \leq \int_a^{\bar{b}} f d\alpha < \infty.$$

If $\int_{-a}^b f d\alpha = \int_a^{\bar{b}} f d\alpha$ we say that f is **Riemann-Stieltjes integrable** over $[a, b]$ and $\int_a^b f d\alpha = \int_{-a}^b f d\alpha = \int_a^{\bar{b}} f d\alpha$.

Notice that if: $m = \min(m_1, m_2, \dots, m_n)$

$$M = \max(M_1, M_2, \dots, M_n)$$

then: $m(\alpha(b) - \alpha(a)) \leq \int_{-a}^b f d\alpha \leq \int_a^{\bar{b}} f d\alpha \leq M(\alpha(b) - \alpha(a))$.

If $\alpha(x) = x$ then we get the usual Riemann integral.

Ex. If $c \in \mathbb{R}$, then $\int_a^b c d\alpha = c(\alpha(b) - \alpha(a))$.

For any partition P we have:

$$\begin{aligned} U_\alpha(f, [a, b]) &= \sum_{i=1}^n M_i(\alpha(x_i) - \alpha(x_{i-1})) \\ &= \sum_{i=1}^n c(\alpha(x_i) - \alpha(x_{i-1})) \\ &= c[(\alpha(x_1) - \alpha(x_0)) + (\alpha(x_2) - \alpha(x_1)) + \dots + (\alpha(x_n) - \alpha(x_{n-1}))] \\ &= c(\alpha(x_n) - \alpha(x_0)) = c(\alpha(b) - \alpha(a)) \end{aligned}$$

$$\begin{aligned} L_\alpha(f, [a, b]) &= \sum_{i=1}^n m_i(\alpha(x_i) - \alpha(x_{i-1})) \\ &= \sum_{i=1}^n c(\alpha(x_i) - \alpha(x_{i-1})) \\ &= c[(\alpha(x_1) - \alpha(x_0)) + (\alpha(x_2) - \alpha(x_1)) + \dots + (\alpha(x_n) - \alpha(x_{n-1}))] \\ &= c(\alpha(x_n) - \alpha(x_0)) = c(\alpha(b) - \alpha(a)). \end{aligned}$$

$$\text{Thus } \int_{-a}^b f d\alpha = \sup_P L_\alpha(c, P) = c(\alpha(b) - \alpha(a))$$

$$\int_a^{\bar{b}} f d\alpha = \inf_P U_\alpha(c, P) = c(\alpha(b) - \alpha(a))$$

$$\text{So } \int_a^b f d\alpha = c(\alpha(b) - \alpha(a)).$$

Let P be any partition of $[a, b]$. We can always refine a partition by adding a point (or points).

Proposition: If P' is a refinement of P (i.e. P' contains all of the points of P plus others) then $L_\alpha(f, P') \geq L_\alpha(f, P)$ and $U_\alpha(f, P') \leq U_\alpha(f, P)$.

Proof. Choose any subinterval $x_{i-1} \leq x \leq x_i$ and add a point t .

$$\text{Let } m_i' = \inf_{x_{i-1} \leq x \leq t} f(x) \quad \text{and} \quad m_i'' = \inf_{t \leq x \leq x_i} f(x).$$

Then $m_i' \geq m_i$ and $m_i'' \geq m_i$.

Now just using the interval $x_{i-1} \leq x \leq x_i$ we have:

$$\begin{aligned} L_\alpha(f, P') &= m'_i(\alpha(t) - \alpha(x_{i-1})) + m''_i(\alpha(x_i) - \alpha(t)) \\ &\geq m_i(\alpha(t) - \alpha(x_{i-1})) + m_i(\alpha(x_i) - \alpha(t)) \\ &= m_i(\alpha(x_i) - \alpha(x_{i-1})) = L_\alpha(f, P). \end{aligned}$$

A similar argument shows $U_\alpha(f, P') \leq U_\alpha(f, P)$.

Since $\int_{-a}^b f d\alpha = \sup_P L_\alpha(f, P)$ and $\int_a^{\bar{b}} f d\alpha = \inf_P U_\alpha(f, P)$

it never "hurts" to refine a partition.

Corollary: For any partitions P, Q , $L_\alpha(f, P) \leq U_\alpha(f, Q)$.

Proof. $L_\alpha(f, P) \leq L_\alpha(f, P \cup Q) \leq U_\alpha(f, P \cup Q) \leq U_\alpha(f, Q)$.

Ex. Suppose $s \in [a, b]$ and $\alpha(x) = 1$ if $x > s$
 $= 0$ if $x \leq s$.

Also assume that $f(x)$ is continuous at $x = s$.

Find $\int_a^b f(x) d\alpha$.

Let P be any partition. If s is not part of P , create a refinement of P that contains s .

Let's say that $x_k = s$. Then notice that $\alpha(x_i) - \alpha(x_{i-1}) = 0$ unless $i = k + 1$, in which case it equals 1.

Thus we have:

$$U_\alpha(f, [a, b]) = \sum_{i=1}^n M_i (\alpha(x_i) - \alpha(x_{i-1})) = M_{k+1}$$

$$L_\alpha(f, [a, b]) = \sum_{i=1}^n m_i (\alpha(x_i) - \alpha(x_{i-1})) = m_{k+1}.$$

Since $f(x)$ is continuous at $x = s$ we know that $\lim_{x \rightarrow s^+} f(x) = f(s)$.

Claim: $\lim_{x \rightarrow s^+} M_{[s,x]} = f(s)$, and $\lim_{x \rightarrow s^+} m_{[s,x]} = f(s)$, where
 $M_{[s,x]} = \sup\{f(t) \mid s \leq t \leq x\}$ and $m_{[s,x]} = \inf\{f(t) \mid s \leq t \leq x\}$

Since $\lim_{x \rightarrow s^+} f(x) = f(s)$ given any $\epsilon > 0$ there exists a $\delta > 0$ such that if $s < x < s + \delta$ then $|f(s) - f(x)| < \epsilon$.

But this implies that if $s < x < s + \delta$ then $\sup_{s \leq t \leq x} |f(s) - f(t)| \leq \epsilon$.

Thus we have: if $s < x < s + \delta$ then $|f(s) - M_{[s,x]}| \leq \epsilon$.

Similarly, if $s < x < s + \delta$ then $\inf_{s \leq t \leq x} |f(s) - f(t)| \leq \epsilon$ and hence

$$|f(s) - m_{[s,x]}| \leq \epsilon.$$

Thus we have $\lim_{x \rightarrow s^+} M_{[s,x]} = f(s)$, and $\lim_{x \rightarrow s^+} m_{[s,x]} = f(s)$.

Thus as we take more refinements of P , M_{k+1} and m_{k+1} will converge to $f(s)$.

Hence

$$\int_a^{\bar{b}} f d\alpha = \inf_P U_\alpha(f, P) = f(s) \quad \int_{-\alpha}^b f d\alpha = \sup_P L_\alpha(f, P) = f(s).$$

Thus $\int_a^b f(x) d\alpha = f(s)$.

Ex. Suppose $s \in [a, b]$ and $\alpha(x) = 1$ if $x > s$
 $= 0$ if $x \leq s$.

a. Determine if $f(x) = 3$ if $x > s$
 $= 1$ if $x \leq s$
 is Riemann-Stieltjes integrable on $[a, b]$.
 If so find $\int_a^b f(x) d\alpha$.

b. Determine if $g(x) = 3$ if $x \geq s$
 $= 1$ if $x < s$
 is Riemann-Stieltjes integrable on $[a, b]$.
 If so find $\int_a^b g(x) d\alpha$.

- a. As in the previous example, let P be any partition and let $x_k = s \in P$, then the only non-zero values for the M_i 's and m_i 's are M_{k+1} and m_{k+1} .

$$M_{k+1} = 3, \quad \text{so} \quad \int_a^{\bar{b}} f d\alpha = \inf_P U_\alpha(f, P) = 3$$

$$m_{k+1} = 1 \quad \text{so} \quad \int_{-a}^b f d\alpha = \sup_P L_\alpha(f, P) = 1$$

So f is not Riemann-Stieltjes integrable on $[a, b]$.

- b. In this case g is continuous from the right and we have

$$M_{k+1} = 3, \quad \text{so} \quad \int_a^{\bar{b}} g d\alpha = \inf_P U_\alpha(g, P) = 3$$

$$m_{k+1} = 3 \quad \text{so} \quad \int_{-a}^b g d\alpha = \sup_P L_\alpha(g, P) = 3$$

Thus g is Riemann-Stieltjes integrable on $[a, b]$ and $\int_a^b g(x) d\alpha = 3$.

Def. $R_\alpha[a, b]$ denotes all bounded functions on $[a, b]$ which are Riemann-Stieltjes integrable with respect to α .

When $\alpha(x) = x$, we write $R[a, b]$ for the space of bounded Riemann integrable functions.

Notice that $R_\alpha[a, b] \subseteq B[a, b]$ = bounded functions on $[a, b]$.

Theorem: Let $\alpha: [a, b] \rightarrow \mathbb{R}$ be increasing. A bounded function $f: [a, b] \rightarrow \mathbb{R}$ is in $R_\alpha[a, b]$ if and only if, given $\epsilon > 0$, there exists a partition P of $[a, b]$ such that $U_\alpha(f, P) - L_\alpha(f, P) < \epsilon$.

Proof. Suppose $f \in R_\alpha[a, b]$ and let $I = \int_a^b f(x) d\alpha$. Let's show that there exists a partition P of $[a, b]$ such that $U_\alpha(f, P) - L_\alpha(f, P) < \epsilon$.

Given $\epsilon > 0$, choose partitions P and Q of $[a, b]$ such that

$$I - \frac{\epsilon}{2} < L_\alpha(f, P) \quad \text{and} \quad U_\alpha(f, Q) < I + \frac{\epsilon}{2}.$$

We know we can do this because

$$\int_a^b f d\alpha = \inf_P U_\alpha(f, P) = \sup_P L_\alpha(f, P).$$

The partition $P' = P \cup Q$ will have:

$$U_\alpha(f, P') \leq U_\alpha(f, Q) < I + \frac{\epsilon}{2} < L_\alpha(f, P) + \epsilon \leq L_\alpha(f, P') + \epsilon.$$

So $U_\alpha(f, P') - L_\alpha(f, P') < \epsilon$.

Now assume for every $\epsilon > 0$ there is a partition P for which

$U_\alpha(f, P) - L_\alpha(f, P) < \epsilon$. Let's show that $f \in R_\alpha[a, b]$.

Since: $L_\alpha(f, P) \leq \int_{-a}^b f d\alpha \leq \int_a^{\bar{b}} f d\alpha \leq U_\alpha(f, P)$, for any partition P , we have

$$0 \leq \int_a^{\bar{b}} f d\alpha - \int_{-a}^b f d\alpha \leq U_\alpha(f, P) - L_\alpha(f, P) < \epsilon.$$

Since this is true for any $\epsilon > 0$, $\int_a^{\bar{b}} f d\alpha = \int_{-a}^b f d\alpha$, and $f \in R_\alpha[a, b]$.

Ex. Let $\alpha(x) = x$ and

$$\begin{aligned} f(x) &= 1 & \text{if } x = 0 \\ &= 0 & \text{if } x > 0. \end{aligned}$$

Show that $f(x) \in R_\alpha[0,1]$.

Let $\epsilon > 0$ be given.

Choose $n \in \mathbb{Z}^+$ such that $\frac{1}{n} < \epsilon$.

Let $P = \{0, \frac{1}{n}, \frac{2}{n}, \frac{3}{n}, \dots, 1\}$ be a partition of $[0,1]$.

Notice that for this partition P we have:

$$\begin{aligned} U_\alpha(f, P) &= \sum_{i=1}^n M_i(\alpha(x_i) - \alpha(x_{i-1})) \\ &= \sum_{i=1}^n M_i(x_i - x_{i-1}) \\ &= (x_1 - x_0) = \frac{1}{n} \end{aligned}$$

$$\begin{aligned} L_\alpha(f, P) &= \sum_{i=1}^n m_i(x_i - x_{i-1}) \\ &= 0. \end{aligned}$$

So we have:

$$U_\alpha(f, P) - L_\alpha(f, P) = \frac{1}{n} < \epsilon.$$

Thus $f(x) \in R_\alpha[0,1]$.

Theorem: $C[a, b] \subseteq R_\alpha[a, b]$.

Proof. Let $f \in C[a, b]$ and let $\epsilon > 0$.

Since f is continuous on a closed, bounded interval (a compact set) it is uniformly continuous on $[a, b]$.

Thus we can choose a $\delta > 0$ such that if $|x - y| < \delta$ then

$$|f(x) - f(y)| < \frac{\epsilon}{\alpha(b) - \alpha(a)}.$$

If P is any partition with $x_i - x_{i-1} < \delta$, for all i , then $M_i - m_i \leq \frac{\epsilon}{\alpha(b) - \alpha(a)}$ for all i and:

$$\begin{aligned} U_\alpha(f, P) - L_\alpha(f, P) &= \sum_{i=1}^n (M_i - m_i) \Delta\alpha_i; \text{ where } \Delta\alpha_i = \alpha(x_i) - \alpha(x_{i-1}) \\ &\leq \frac{\epsilon}{\alpha(b) - \alpha(a)} \sum_{i=1}^n \Delta\alpha_i \\ &= \frac{\epsilon}{\alpha(b) - \alpha(a)} (\alpha(b) - \alpha(a)) = \epsilon. \end{aligned}$$

Thus $f \in R_\alpha[a, b]$.

Ex. Here's an example of a bounded function that is not Riemann-Stieltjes integrable with respect to any nonconstant increasing α .

$$\begin{aligned}\chi_{\mathbb{Q}}(x) &= 1 && \text{if } x \in \mathbb{Q} \cap [a, b] \\ &= 0 && \text{if } x \notin \mathbb{Q} \cap [a, b].\end{aligned}$$

In any partition $P = \{x_0, x_1, \dots, x_n\}$ of $[a, b]$, every subinterval $x_{i-1} \leq x \leq x_i$ will contain both rational and irrational numbers.

Thus $M_i = 1$ and $m_i = 0$ for all i . So we have:

$$L_{\alpha}(\chi_{\mathbb{Q}}, P) = \sum_{i=1}^n m_i(\alpha(x_i) - \alpha(x_{i-1})) = 0.$$

$$\begin{aligned}U_{\alpha}(\chi_{\mathbb{Q}}, P) &= \sum_{i=1}^n M_i(\alpha(x_i) - \alpha(x_{i-1})) \\ &= \sum_{i=1}^n (\alpha(x_i) - \alpha(x_{i-1})) \\ &= \alpha(b) - \alpha(a) \neq 0\end{aligned}$$

Thus $\inf_P U_{\alpha}(\chi_{\mathbb{Q}}, P) = \alpha(b) - \alpha(a) \neq 0$ (since $\alpha(x)$ is increasing and non-constant)

$$\sup_P L_{\alpha}(\chi_{\mathbb{Q}}, P) = 0.$$

So $\int_{-a}^b \chi_{\mathbb{Q}} d\alpha \neq \int_a^{\bar{b}} \chi_{\mathbb{Q}} d\alpha$ and $\chi_{\mathbb{Q}}$ is not Riemann-Stieltjes integrable.

Ex. Let $\alpha(x) = \chi_{(1,2]} = 1$ if $1 < x \leq 2$
 $= 0$ otherwise.

Show that $f(x) \in R_\alpha[0,2]$ if and only if $\lim_{x \rightarrow 1^+} f(x) = f(1)$.

We can always choose a partition P of $[0,2]$ that includes the point $x_k = 1$. Then we have:

$$L_\alpha(f, P) = \sum_{i=1}^n m_i (\alpha(x_i) - \alpha(x_{i-1})).$$

Since $\alpha(x) = 0$ for $x \leq 1$ and $\alpha(x) = 1$ for $1 < x \leq 2$, then the only nonzero contribution comes from $\alpha(x_{k+1}) - \alpha(x_k) = 1$.

Hence:

$$L_\alpha(f, P) = m_{k+1}.$$

Similarly, $U_\alpha(f, P) = \sum_{i=1}^n M_i (\alpha(x_i) - \alpha(x_{i-1})) = M_{k+1}.$

From our earlier theorem we know that f is Riemann-Stieltjes integrable if and only if given any $\epsilon > 0$ there exists a partition P such that $U_\alpha(f, P) - L_\alpha(f, P) < \epsilon$.

Thus we must show given any $\epsilon > 0$ there exists a partition P such that $M_{k+1} - m_{k+1} < \epsilon$ if and only if $\lim_{x \rightarrow 1^+} f(x) = f(1)$.

Given $\epsilon > 0$, assume there is a partition, P , such that if $M_{k+1} - m_{k+1} < \epsilon$ and let's show that $\lim_{x \rightarrow 1^+} f(x) = f(1)$.

Since $M_{k+1} = \sup_{1 \leq x \leq x_{k+1}} f(x)$, $m_{k+1} = \inf_{1 \leq x \leq x_{k+1}} f(x)$, we have:

$$|f(x) - f(1)| \leq M_{k+1} - m_{k+1} < \epsilon \quad \text{for } 1 \leq x \leq x_{k+1}.$$

So if we choose $0 < \delta < x_{k+1} - 1$ we get for $1 \leq x < 1 + \delta < x_{k+1}$

$$|f(x) - f(1)| < \epsilon$$

and thus $\lim_{x \rightarrow 1^+} f(x) = f(1)$.

Now assume $\lim_{x \rightarrow 1^+} f(x) = f(1)$ and let's show that there exists a partition P such that $M_{k+1} - m_{k+1} < \epsilon$.

Since $\lim_{x \rightarrow 1^+} f(x) = f(1)$ we know that given any $\epsilon > 0$ there exists a $\delta' > 0$ such that if $1 < x < 1 + \delta'$ then $|f(x) - f(1)| < \frac{\epsilon}{2}$.

Notice that this means that if $1 < x < 1 + \delta'$

$$|M_{[1,x]} - f(1)| \leq \frac{\epsilon}{2} \quad \text{and} \quad |f(1) - m_{[1,x]}| \leq \frac{\epsilon}{2}.$$

So choose $\delta = \delta'$ then we have:

$$\begin{aligned} |M_{[1,x]} - m_{[1,x]}| &\leq |M_{[1,x]} - f(1)| + |f(1) - m_{[1,x]}| \\ &\leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon. \end{aligned}$$

Thus if we choose a partition, P , so that $1 < x_{k+1} < 1 + \delta$ then:

$$M_{k+1} - m_{k+1} \leq \epsilon.$$

Thus $f(x) \in R_\alpha[0,2]$ if and only if $\lim_{x \rightarrow 1^+} f(x) = f(1)$.
